#### Abstract

Ever since the Supreme Court instituted the one person, one vote principle in congressional elections based on its decision in Wesberry $v$. Sanders (1964), intrastate deviations from equal district populations have become smaller and smaller after each decennial reapportionment. Relying on equal total population as the standard to meet the Court's one person, one vote principle, though, raises serious constitutional questions stemming from, most basically, not every person has the right to vote. As such, the application of the equal population rule creates a considerable level of malapportionment across districts, both within and between states. This study systematically analyzes the differences between district total populations vs. district voting age populations (VAPs), documenting just how far off the use of the district total population is from the one person, one vote principle. Further, we consider how congressional reapportionments would change if instead of total state population, the measure for redistributing seats was based on the VAP and the voting eligible population (VEP). The analyses are performed for each reapportionment year beginning in 1972. Line drawers can do a much better job at meeting the Court's one person, one vote principle by relying on better measures of voter equality and that by failing to do this, we are much further away than we need to be in trying to meet the one person, one vote standard.

Keywords: reapportionment, malapportionment, redistricting, equal population, voting age population, voting eligible population, U.S. House elections

[^0]As any introductory American government textbook explains, the issue of representation carried the most importance among the various debates at the 1787 Constitutional Convention. The opposing positions of delegates representing large states (i.e., Virginia) and small states (i.e., New Jersey) were eventually resolved, appropriately enough by the Connecticut Compromise, a medium-sized state led by Roger Sherman, who successfully advocated for an upper chamber with representation set at two Senators per state and a lower chamber whose representation was based on a state's population. This "Great Compromise" not only mollified the concerns of representation tied to population, but just as fundamental, by denoting slaves as three-fifths of a person, the opposing interests of northern and southern delegates were temporarily assuaged.

The laws guiding the selection of candidates determine which voters have the most influence in affecting the political process and by extension the type, quality, and tenor of representation, and therefore it is no surprise that the question of representation was the Founders' greatest concern. But until the mid 1960s, U.S. House representation was tied more to geography than it was to the number of voters in any given congressional district. By mandating a decennial census, the Constitution guaranteed apportionment of congressional seats according to a state's population, but rare was the state that considered reallocating its districts in accordance with a nod toward population equality. Rather the status quo was generally upheld, and this meant the incorporation of a new U.S. House seat was often done by making it an at-large district-covering the entire state.

Population equality was not a particularly valued principle and often it was actively opposed by northern and southern politicians alike, since most represented districts with proportionally fewer residents outside of major urban centers, where rural voters' interests received outsized attention (see Ansolabehere, Gerber, and Snyder 2002). In partisan terms,
this meant that congressional districts in the North were biased in favor of Republicans and U.S. House boundaries in the South perpetuated the longstanding hegemony of rural Democrats (Cox and Katz 2002).

Failure to adjust district boundaries to satisfy a principle of population equality was met with growing resistance among those constituents residing in more populous metropolitan settings, and in 1946 the Supreme Court addressed the issue of district malapportionment. In the famous 4-to-3 decision handed down by Justice Frankfurter in Colegrove v. Green, the Supreme Court chose not to wade into the "political thicket" of setting the criteria for crafting legislative districts. Of course the ruling in this case was not the last word, and in the 1962 Baker v. Carr decision not only did the Court deem redistricting a justiciable issue but endorsed a principle of apportionment based on the criterion that each person deserved an equal vote (Levinson 1985). Hence the principle of one person, one vote was established.

In this study we seek to accomplish two primary objectives. First, we contend that the approach to meeting the one person, one vote principle is misguided because it is based on a markedly inferior measure. Because the purpose of the rule is to ensure that each individual has an equal influence on determining who represents them, we can get closer to meeting this lofty standard by using voting age population (VAP). Second, we use data at the district- and state-level to determine the amount of deviation from the one person, one vote principle with intrastate and interstate analyses, respectively. The intrastate analysis shows that despite notable reductions in district deviations from equal population, there has not been a corresponding decline in deviations away from equal voting age population. The interstate analysis reveals that reapportionments based on the VAP and voting eligible
population (VEP) would considerably alter the redistribution of U.S. House seats and this would marginally benefit the Democratic Party in presidential elections.

## The Reapportionment Revolutions

In this section we discuss the historical and political contexts that shaped the legal arguments propping up the two major pillars guiding contemporary congressional reapportionment: equal population and safeguards for minority voting rights.

Scholars speak of Baker v. Carr as initiating a revolution (Cox and Katz 2002; Fenno 1978), because of its wide reaching effects on district-based elections. The reassignment of residents on the basis of equal population clearly could and would, alter the outcomes of elections both in terms of the incumbency advantage (Desposato and Petrocik 2003) and partisan control (McKee 2008). But this was not the only reapportionment revolution. Thirty years after Baker v. Carr, with the equal population rule firmly in place, the second reapportionment revolution occurred with the massive increase in the number of majorityminority districts created for the 1992 congressional elections (McKee 2004).

The principle guiding the first reapportionment revolution was of course technically colorblind, but the context surrounding its advocacy had much to do with the issue of race (Levinson 2002). Especially in southern states, congressional district populations variedly enormously (Bullock 2010). This was not by accident, rather the historical strength of the Democratic Solid South resided in rural counties that often contained relatively large, and primarily disfranchised, African American populations (Key 1949). The whites in these rural settings knew that readjustment of district boundaries on the basis of equal population would weaken their hold on political power. Not surprisingly, the triumvirate of cases (Baker v. Carr, Reynolds v. Sims; Wesberry v. Sanders) forming the backbone of the one person, one vote
standard involved lawsuits from southern states (Tennessee, Alabama, and Georgia, respectively). Redrawing district lines to better suit the one person, one vote rule would eventually bolster the clout of African Americans (Bullock and Gaddie 2009) and whites residing in burgeoning metropolitan areas (Black and Black 2002).

Enforcement of the equal population rule as espoused in Baker, centered on the simple counting of the number of people residing in a given district. As we will demonstrate, compliance with this standard has increased with every subsequent reapportionment in response to essentially a zero tolerance policy laid out by the Supreme Court in Karcher v. Daggett (1983). In this case the Court ruled that even miniscule deviations from equal population violated the Constitution because the state of New Jersey could clearly comply with implementing a plan with more equal district populations.

With practically no justifiable wiggle room from the equal population standard established by the Court in Karcher, the question of minority vote dilution reemerged in the 1986 case of Thornburg v. Gingles. Responding to a history of southern apportionment and redistricting schemes that were devised to weaken the likelihood that African Americans would have the opportunity to elect candidates of their choice (see Davidson 1984; Parker 1990), in Thornburg v. Gingles ${ }^{1}$ the Supreme Court laid out a set of criteria, that if met, would allow for the creation of districts controlled by minority populations (for details see Butler 2002; McKee and Shaw 2005). Because of the timing of the decision, the 1992 U.S. House elections would be the first to occur with a large expansion in the number of newly created majority-minority districts.

Table 1 displays data on the number of majority black and majority Hispanic congressional districts (according to voting age population) from 1972 to 2002. Whereas

[^1]there were eight majority black districts in 1972 and twelve in 1982, in the wake of the Thornburg decision the number increased to 27 in 1992. Most of the new majority black districts were located in southern states covered by the 1965 Voting Rights Act (VRA). Under the Preclearance Provision in Section 5 of the VRA, the Department of Justice oversees redistricting plans and during the 1990s round it insisted that certain southern states maximize their number of majority black districts (Bullock 2010; Butler 2002; Cunningham 2001). In 2002 the total is reduced to 21 and the decline was a response to the Shaw $v$. Reno (1993) decision and subsequent rulings (e.g., Miller v. Johnson 1995; Bush v. Vera 1996; Hunt v. Cromartie 2001) that declared several majority black districts unconstitutional racial gerrymanders (see Butler 2002).
(Table 1 here)
In contrast with majority black districts, the large jump in the number of majority Hispanic districts from $1982(\mathrm{~N}=6)$ to $1992(\mathrm{~N}=16)$ is followed by another increase to 21 in the 2002 elections. Also, the average percent Hispanic is notably higher and actually goes up after 1982, while the maximum, minimum, range, and standard deviations remain much higher than the corresponding statistics for majority black districts. One obvious explanation for the differences is that Hispanic populations have much higher rates of non-citizen voting age populations and this is taken into account when the purpose is to give Hispanics the opportunity to elect representatives of their choice.

Against the backdrop of the equal population rule, the increase in majority-minority districts, as numerous studies have documented (Black and Black 2002; Lublin 1997; Epstein and O’Halloran 1999; Hill 1995; Petrocik and Desposato 1998), necessarily reduced the overall number congressional districts won by Democratic candidates. This was so because minority voters, especially African Americans, are the most Democratic in their voting
preferences and thus concentrating them into fewer districts increased the portion of Republican voters in adjoining districts.

The progression of case law squarely rests the metric of the one person, one vote principle on counting the total population in a state and then dividing it by the assigned number of congressional districts. By contrast, the question of apportioning districts where minority vote dilution comes into play is an ever-evolving legal issue. Suffice it to say that it has become a highly contentious and partisan-laden dispute because the concentration of minority populations generally benefits the Republican Party in congressional elections, at least in the aggregate (but see Shotts 2001).

## Empirical Assessments of the One Person, One Vote Principle

We seek to determine the extent to which congressional districts deviate from the one person, one vote principle on the basis of VAP. Specifically, we begin with an analysis that shows just how much variability exists between a measure of equal district population versus one based on the district voting age population. The disparities we uncover are notable because the VAP standard gets us closer to the one person, one vote ideal. Second, we demonstrate what the reapportionment of House seats would look like if it were based on the VAP and the VEP, instead of merely total population, and what the implications would be for the partisan allocation of Electoral Votes.

## Intrastate Deviations

Beginning with Wesberry and continuing through current jurisprudence, the Court has insisted that U.S. House districts within a state be drawn, as mathematically as possible, with equal populations. This constitutional requirement has become increasingly refined since the

1960s equality revolution because (1) the Census has provided considerably more micro-level data and (2) these data work in conjunction with advances in computer software technologies that employ Geographic Information Systems (GIS) to map populations. Today, the constitutional standard of population equality is interpreted for most states ${ }^{2}$ to mean that a state's congressional districts should not deviate in their apportionment population by more than a single person. ${ }^{3}$
(Table 2 here)
Table 2 documents the increasing precision with which "one-person, one-vote" has been applied. In 1972, the first reapportionment and redistricting after Wesberry, $82.4 \%$ of congressional House districts deviated from their state's ideal district population by less than $0.25 \%$ and the average deviation for all House districts was $0.81 \%$. Yet, in 1972 , there were still $4.5 \%$ of districts that deviated by $1 \%$ or more from this standard and a maximum deviation of $7.34 \%$. As the Courted continued to press for greater and greater equality, the rates and size of deviation dropped precipitously. After the 2002 reapportionment, $99.3 \%$ of all House districts were within $0.25 \%$ of their state's ideal populations. In fact, the average deviation for all House districts was just $0.05 \%$; the maximum deviation was just $0.66 \%$.

By many measures the "one-person, one-vote" revolution has been a tremendous success. It eliminated the democratically corrupting practice of "silent gerrymandering" that allowed for increasingly rotten districts to proliferate as well as the partisan advantages that they engendered. It avoided the "political thicket," of which Justice Frankfurter was so fearful in Colegrove v. Green (1946), by reengaging the political practice of redistricting. And, it

[^2]reduced the deviation in apportionment populations in states' House districts to nearly zero. Chief Justice Earl Warren, in fact, wrote in his Memoirs that the seminal Baker decision was the most important decision in his entire tenure on the Court-more so than, for instance, Brown v. Board of Education (1954), Gideon v. Wainwright (1963), or Miranda v. Arizona (1966). In summing these accomplishments, Ansolabehere and Snyder (2008) conclude that American democracy is entering an "age of fairness" and the end of inequality.

Table 2 clearly demonstrates that inequality is nearly vanquished-at least as measured by the number of individuals in the congressional districts for each state. But, this measure does not equate to the constitutional standard of "one person, one vote." As Levinson $(2002,1270)$ argues, this standard "most certainly does not hold true either as a description of the electorate or even as a normative guide to deciding which persons should be awarded the franchise and what weight their votes should actually have in the electoral process." In other words and in the most basic interpretation, the numerical count for the standard-the apportionment population-includes many "persons" who cannot vote, for instance, individuals below the age of 18 , individuals who are not U.S. citizens, and many felons. This is considerably more than a semantic concern-in other words, perhaps "one person, one vote" was just a poor choice of words. The constitutional and normative underpinnings of the standard are central to the efficacy of a democracy: equality and the right to vote. Levinson concludes by arguing that the constitutional standard of "one person, one vote" is a democratic mantra in need of a meaning.
(Table 3 here)
Table 3 provides the most straightforward data that taps into this concern that is available for congressional districts: voting age population (VAP). Table 3 provides a similar breakdown of states' districts as Table 2, but now with the VAP as the unit of analysis. In

1972, just $57.86 \%$ of House districts were within $0.25 \%$ of their state's ideal VAP. ${ }^{4}$
Furthermore, $32.38 \%$ of the districts had VAPs that deviated by $1.0 \%$ or more from their state's ideal VAP, of which $5.95 \%$ deviated by $5 \%$ or more. The greatest deviation in 1972 was $18.19 \%$.

The deviations in Table 2 are greatest in 1972, but the apportionment population deviations were still considerably smaller than these corresponding VAP deviations displayed in Table 3. In addition, the apportionment population deviations were minimized over time, but these VAP deviations have not been systematically reduced. In 2002, the percent of districts within the $0.25 \%$ threshold actually decreased to $57.51 \%$ compared to $99.3 \%$ for the comparable statistic in Table 2, and $26.29 \%$ of the districts were above the $1 \%$ threshold. The maximum deviation in 2002 was $13.06 \%$.

These VAP deviations are considerable and stand in sharp contrast with the results from Table 2. Specifically, instead of witnessing the diminishing deviations in apportionment populations over time, variations in states' district VAPs show little change over time as well as a wide variation in districts' VAP. Together, these Tables imply that the constitutional standard of "one person, one vote" is currently far from being met. Despite the strict overall population equality of districts within states, these figures show that some districts are "packed" with more minors who cannot vote and some with fewer minors-up to almost $10 \%$ difference between districts within a state. In districts that are packed with relatively more minors, there are fewer remaining potential voters as compared to districts with relatively fewer minors. This results in the over-representation of the former voters and the under-representation of the latter voters.

[^3]The presence of demonstrable and predictable variation in the VAP among various societal groups-including those protected by the VRA—produces, be it random or systematic, malapportioned districts and vote dilution, which Baker and subsequent decisions declared unconstitutional. Basing redistricting on the VAP would not eliminate all of the intrastate malapportionment for potential voters, but it certainly would bring states' districts in closer compliance with the words and meaning of "one person, one vote."

## Interstate Deviations

The above section documents the presence of consistent and considerable intrastate malapportionment at levels far greater than those declared unconstitutional. Intrastate malapportionment, though, is but one form of malapportionment. However, it is the form that is almost exclusively considered by the Court, politicians, and scholars. Interstate malapportionment is the population deviation among the states. For example, after the 2000 reapportionment and the equalization of apportionment populations within states (as demonstrated in Table 2), the maximum deviation in the ideal population sizes of state districts was 410,012 individuals, which is $63.38 \%$ of the national ideal size. This deviation is about $9600 \%$ larger than the deviation declared unconstitutional in Karcher and over 41 million $\%$ larger than the typical intrastate deviation allowed today (Ladewig and Jasinski 2008; Ladewig 2011).

The current levels of interstate malapportionment persist and grow despite the Court's efforts in minimizing the intrastate malapportionment of the apportionment population. As Table 3 displays, though, there is further variation among the states' VAPs. Given the distribution of House seats after the 2000 reapportionment, interstate malapportionment as measured with the VAP of each state actually increases above the
figures in the preceding paragraph (See Appendix 1 through 3 for details). The maximum deviation in states' ideal VAPs increases to $64.04 \%$ of the national ideal district size.

As mentioned, the VAP is still not an entirely accurate enumeration of potential voters-though certainly better than apportionment population-but it includes noncitizens, felons, etc. The measure Voting Eligible Population (VEP) is much closer to the constitutional standard of "one person, one vote." And, the 2000 interstate malapportionment figures increase again if VEP is used for each state. In this case, the maximum deviation in states' ideal VEP jumps to $71.91 \%$ of the national ideal district size. Given the state variations in population, eligibility, and the number of House districts, the 2000 apportionment provides each eligible voter in Nevada with exactly twice the voting power of each eligible voter in Montana. It is difficult to reconcile the current implementation of "one person, one vote" when these variations create foreseeable results in which "one Nevadan, two votes" vis-à-vis a Montanan.

Focusing on potential voters, either with the VAP or the VEP, in order to better approximate "one person, one vote" would have deep implications for interstate reapportionment. Tables 4 through 7 provide the number of House seats that each state would receive in each reapportionment from 1970 to $2000^{5}$ as well as the number of seat changes among the three population measures: Apportionment Population (AP) - which is currently used, VAP, and VEP. ${ }^{6}$ (See Appendix 4 through 7b for details.) Specifically, in 1970 if the U.S. House had been apportioned with VAP instead of AP, 10 House seats would have been changed: five states (CT, NJ, NY, OR, and PA) would have gained seats and five states (LA, MI, SC, SD, and TX) would have lost one seat. In 1980, there is a 6 -seat difference

[^4]between AP and VAP, a 10 -seat difference between AP and VEP, and a 10 -seat difference between VAP and VEP. Overall, the apportionment of 11 states is affected by the method used.
(Tables 4 through 7 here)
The question of which population to use, becomes more consequential for the 1990 and 2000 reapportionments. For the 1990 reapportionment, there would have been 10 seat changes if VAP would had been used instead of AP, 18 seat changes if VEP would had been used instead of AP, and 18 seat changes if VEP would have been used instead of VAP. Overall, the population used affects the apportionment of 17 states. And, for the 2000 reapportionment, there would have been 6 seat changes if VAP would had been used instead of AP, 40 seat changes if VEP would had been used instead of AP, and 36 seat changes if VEP would have been used instead of VAP. Overall, the population used affects the apportionment of nearly half of the country ( 23 states). For example, California has a high of 53 seats (AP) and a low of 45 seats (VEP).

Changing the population used for the apportionment from, say, AP to VAP or VEP would bring the practice of apportionment closer in line with the normative meaning of "one person, one vote." It would also bring it numerically closer. In 2000, if the VEP was used as the apportionment population (resulting in the district distribution found in Table 7), the interstate malapportionment measurement of the maximum deviation in states' ideal VEP would drop to $52.19 \%$ of the national ideal district size (See Appendix 8 and 9 for details). Any change would also have many effects in the U.S. Congress and state politics. But, one of the most direct effects would be on the President through the Electoral College.

Table 8 displays the Electoral College vote as it was with the Apportionment Population from 1972 through 2008 as well as recalculates the vote if the House had been
reapportioned with VAP or VEP. If VAP had been used, the vote would have changed in half of the ten Presidential elections. Even though four of the five instances in which a vote change occurred the same President would have been elected, the 2000 Presidential election would have ended in a 268 to 269 split. ${ }^{7}$ This split gives neither George W. Bush nor Al Gore an absolute majority of 270 Electoral College votes to win the Presidency. In this case, the 2000 presidential would have been sent to the U.S. House of Representatives to decide. If the VEP had been the population measure, then four of the seven presidential elections for which we have data would have witnessed a change in the Electoral College vote, but none of the outcomes-including the 2000 election-would have changed. Nonetheless, the U.S. House of Representatives and the Electoral College would have better reflected the democratic principle enshrined in the constitutional standard of "one person, one vote."
(Table 8 here)

## Conclusion

In this study we have taken empirical inventory of the one person, one vote principle in congressional reapportionments. The established legal precedent relies on minimizing deviations away from a measure of total population. To be sure, in states with multiple districts, they now exhibit hardly any deviation from the equal population standard. But we have shown that strict reliance on meeting the equal population standard is misguided, because it has not led to attendant reductions in the variance of voting age populations (VAPs). This is an important finding because the VAP is a better measure for getting closer to complying with the one person, one vote principle.

[^5]In addition to finding that intrastate deviations in the VAP have not been systematically reduced in subsequent congressional reapportionments, we also demonstrate that better measures of state populations indicate that decennial reapportionments would be considerably altered. For instance, if we were to reallocate U.S. House seats on the basis of the VAP or the VEP (voting eligible population), two measures that afford individuals a more "equally weighted" vote, then there would be substantial changes in the redistribution of congressional districts. Further, the differences in seat allocations based on the VAP and VEP have grown in more recent cycles because many of the high population growth states contain social groups with lower citizenship rates and lower VAPs (i.e., Hispanic growth in Arizona and Texas). This means that certain slow growth northern states (like New Jersey and Pennsylvania) with higher VAPs and VEPs are shortchanged congressional representation.

We have also shown that in several presidential elections the two-party Electoral Vote totals would be somewhat altered if we reallocated House seats according to VAP or VEP. And since the high growth states are generally located in the Sun Belt where the GOP is stronger but the resident populations are disproportionately younger8, the redistribution of congressional districts according to the VAP and VEP advantages the Democratic Party since it is electorally stronger in low growth northern states. In fact, if the 2000 presidential election results were based on a congressional reapportionment tied to state voting age population, then neither party would have won an Electoral College majority - meaning the next president would have been determined by the U.S. House of Representatives.

Our findings in this study make it abundantly clear that the current reliance on total population, whether at the district- or state-level is fundamentally misguided. The Census

[^6]provides us with data that allow us to come closer to fulfilling the Court's one person, one vote principle. To be sure, even these more accurate measures that we assess in this paper leave us well short of meeting such a lofty and perhaps impractical standard, but resting the one person, one vote principle on a patently inferior count (total population) not only ensures an unnecessary amount of representational bias in congressional reapportionment but it also allows line drawers considerable leeway to manipulate maps for partisan gain (Winburn 2008).

Notes: Shaded states experience a change in one of the three change measures. CAP: Apportionment Population; VAP: Voting Age Population; VEP: Voting Eliligle Population. 1. Change of VAP - AP; 2. Change of VEP - AP; 3. Change of VEP - VAP.
Table 8. The Electoral College Vote Based on three Different Measures of Reapportioned State Population, 1972-2008

| Measure | 1972 | 1976 | 1980 | 1984 | 1988 | 1992 | 1996 | 2000 | 2004 | 2008 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Apportioned Population |  |  |  |  |  |  |  |  |  |  |
| Democratic Votes | 17 | 297 | 49 | 13 | 111 | 370 | 379 | 266 | 251 | 365 |
| Republican Votes | 520 | 240 | 489 | 525 | 426 | 168 | 159 | 271 | 286 | 173 |
| Winner | R | D | R | R | R | D | D | R | R | D |
| Voting Age Population |  |  |  |  |  |  |  |  |  |  |
| Democratic Votes | 17 | 296 | 49 | 13 | 111 | 372 | 382 | 268 | 251 | 366 |
| Republican Votes | 520 | 241 | 489 | 525 | 426 | 166 | 156 | 269 | 286 | 172 |
| Winner | R | D | R | R | R | D | D | Neither | R | D |
| Voting Eligible Population |  |  |  |  |  |  |  |  |  |  |
| Democratic Votes | - | -- | -- | 13 | 111 | 372 | 379 | 264 | 256 | 368 |
| Republican Votes | -- | -- | -- | 525 | 426 | 166 | 159 | 273 | 281 | 170 |
| Winner | - | -- | -- | R | R | D | D | R | R | D |

NOTE: Data on Electoral Vote returns from 1972-2004 are from CQ's Guide to U.S. Elections (2005) and the 2008 returns are from Dave Leip's Atlas of U.S. Presidential Elections (uselectionatlas.org/RESULTS/). Shaded vote returns indicate a different distribution than the official returns based on the apportioned population. According to a reapportionment based on the VAP, in 2000 there would not have been an outright winner since both Bush and Gore would not have secured a 270 -vote majority. Hence, the contest would have been decided in the U.S. House of Representatives.

Appendix 1. 2000 Interstate Malapportionment: AP Districts and AP Population

| State | Apportionment Population | Number of MCs | Average Population of District | Deviation from Ideal | Absolute Deviation from Ideal | \% Deviation form Ideal |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Alabama | 4,461,130 | 7 | 637,304 | 9,648 | 9,648 | 1.49\% |
| Alaska | 628,933 | 1 | 628,933 | 18,019 | 18,019 | 2.79\% |

[^0]:    - Prepared for the 2012 State Politics and Policy conference in Houston, Texas, February 16-18.

[^1]:    ${ }^{1}$ This was a North Carolina case.

[^2]:    2 Iowa is a notable exception. Iowa passed a state constitutional amendment requiring their House districts to contain whole counties as long as the population deviations are not greater than $1 \%$. The maximum deviation in Iowa's post-2000 districts was 137 individuals.
    3 This deviation is allowed when a state's apportioned population is not perfectly divisible by the number of House districts apportioned to the state.

[^3]:    ${ }^{4}$ Each state is currently required to apportion to the state's ideal population, which is calculated by dividing the state's apportionment population by the number of districts the state will have. The ideal VAP is calculated similarly, the state's total voting age population divided the number of districts that the state will have.

[^4]:    5 The Hill Method of Equal Proportions was used to apportion the 435 -seat House. See U.S. Code 2 Section 2 a .
    ${ }^{6}$ The AP and VAP data are from the U.S. Census. The VEP data are from the Public Mapping Project (see www.publicmapping.org). Unfortunately, the Public Mapping Project does not have VEP for 1970.

[^5]:    ${ }^{7}$ Gore's count includes the faithless elector from Washington D.C. that abstained from the actual 2000 Electoral College vote. However, given the VAP results, she probably would have cast her ballot-thereby giving Gore 269 Electoral Votes. Either way, absolute majority of 270 votes would not have been met by either presidential candidate.

[^6]:    ${ }^{8}$ California is the exception to this rule, a "blue" state with a significantly lower VEP population.

[^7]:    Notes: Shaded states experience a change in one of the three change measures. CAP: Apportionment Population; VAP: Voting Age
